*Department of Muscalinkelesal Radiology, Royal Orthopoedic Hospital, Birmingham, United Kingdom

Numerous corticosteroid preparations are available, but the type and dose administered is frequently at the discretion of the clinician. This is often based on anecdotal evidence and experience rather than formal clinical guidelines. In order to better understand current practice, we anonymously surveyed 100 members of the British Society of Skeletal Radiologists. The results of the survey demonstrated the arbitrary use of all types of steroid preparation at different anatomical locations. In this article, we review the commonly used corticosteroids and propose a guideline to help practitioners decide on the type and dose of steroid depending on the treatment location.

De nombreuses préparations de corticostéroides sont disponibles. Cependant, le type et la dose administrés sont souvent déterminés à la discrétion du clinicien, souvent en fonction de l'expérience et d'observations empiriques et non sur la base de recommandations cliniques officielles. Afin de mieux comprendre la pratique actuelle, les auteurs ont procédé à un sondage anonyme sur 100 membres de la British Society of Skeletal Radiologists. Les résultats ont permis de mettre en évidence une utilisation arbitraire de l'ensemble des types de préparations stéroidiennes, en différents sites anatomiques. Cet article est une synthèse des corticostéroides les plus fréquemment utilisés et propose une recommundation visant à aider les praticiens à sélectionner le type et la dose de stéroides à administer en fonction de la zone traitée. Key Words: Intra-articular injections: Corticosteroids: Evidence-based: Guidelines

It is common practice to use intra-articular (IA) corticosteroids for the treatment of musculoskeletal conditions, and it is one of the commonest drugs administered within a radiology department [1,2]. Injections are performed by various medical and allied health professionals and include IA, bursal, tendon sheath, enthesis, epidural, and soft tissue locations. Evidence supports the use of corticosteroid injection, as its anti-inflammatory properties can provide patients with pain relief, with the aim of improving function [2,3]. Steroid injections into affected joints can allow dose reduction of systemic steroids, as well as orally administered analgesics and anti-inflammatories. Corticosteroid injections (LA), which acts as the solvent for the corticosteroids, provides may temporise the need for surgery or provide relief when surgery is contraindicated for medical reasons. The

therapeutic effects of corticosteroids are, however, often temporary, with some studies suggesting no long-term difference between corticosteroids and placebo [4]. This is not a consistent and universal finding, with results varying with different anatomical sites and indications. To date, no formal evidence-based guidelines exist to guide clinicians in deciding which steroid to inject. There is a lack of evidence and robust studies looking at the comparable safety and efficacy of available agents and the long-term outcomes of corticosteroid injection.

Corticosteroids are often combined with a local anaesthetic volume for the injectate to distribute in the joint, and provides immediate analgesia. This LA phase can allow further clinical assessment regarding symptomatic relief, often giving diagnostic information relating to a potential pain source.

Commonly used LAs are lidocaine, bupivacaine, and ropivacaine; the latter two are longer-acting. Although it is beyond the scope of this review article to discuss in detail the
