Metandienone - WikiMili, The Best Wikipedia Reader

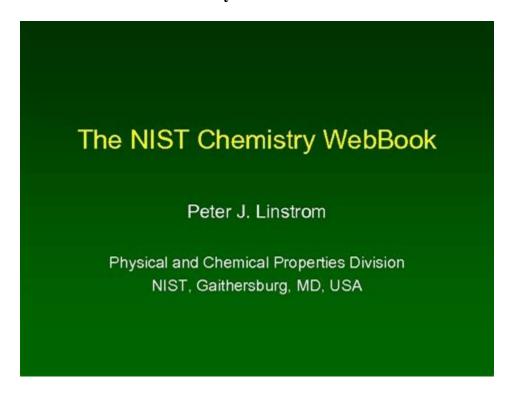

Introduction. The synthetic substances related to the male sex hormones (androgens) are called 'anabolic steroids'. The principal effects of these substances are to promote the growth of skeletal muscle (anabolic effects) and the development of male sexual characteristics (androgenic effects). Developed in the late 1930s, anabolic steroids.

METHANDROSTENOLONE - National Center for Advancing Translational Sciences

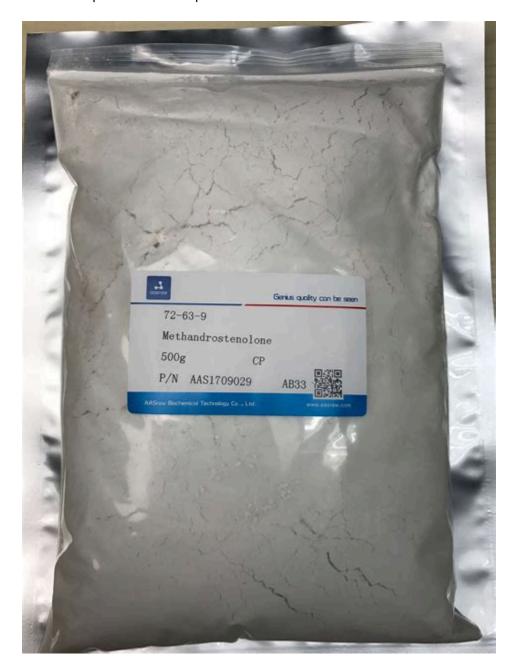

Dianabol Functions & Traits: Methandrostenolone is a testosterone derived anabolic androgenic steroid. Officially, it is a structurally altered form of the primary male androgen testosterone. Dianabol is the testosterone hormone with an added double bond at the carbon one and two position.

Methandrostenolone - NIST Chemistry WebBook

Mestanolone, also known as methylandrostanolone and sold under the brand names Androstalone and Ermalone among others, is an androgen and anabolic steroid (AAS) medication which is mostly no longer used. [1] [2] [3] [4] It is still available for use in Japan however. [2] [3] It is taken by mouth. [4]

Methandrostenolone | C20H28O2 | CID 6300 - PubChem

Metandienone, also known as methandienone or methandrostenolone and sold under the brand name Dianabol among others, is an androgen and anabolic steroid medication which is still quite often used because of its affordability and effectiveness for bulking cycles. It is also used non-medically for physique- and performance-enhancing purposes.

Metandienone | C20H28O2 | ChemSpider

Methasterone, also known as methyldrostanolone and known by the nickname Superdrol, is a synthetic and orally active anabolic-androgenic steroid (AAS) which was never marketed for medical use. It was sold legally for 9 years as a body building supplement.

Prolonged effects of anabolic steroid upon muscular contractile force

ABSTRACT. There is an established body of literature ABSTRACT. There is an established body of literature with respect to the pharmacological properties of anabolic steroids. However, researchers have ignored the possibility of latent behavior of these drogs. The purpose of this study was to investigate the prolonged effect of an anabolic steroid (methandrostenolone) following cessation of drug administration and a 15 week detraining period.

The population consisted of male weightlifters, A sample of twenty subjects ranging in age from 19 to 25 was used. Maximum dynamic nouscular forces were determined by testing 1-RM (Repetition Maximum) in the bench and military presses and the squat exercises. The anabolic steroid, 15 mg of methandrostenolone each day, was administered during consecutive four weeks of train-

was administered during consecutive four weeks of training period which was then followed by a 15-week detraining period.

training period.

The results of the present study revealed that the increase of muscular force obtained during drug administration was significantly maintained following 15 weeks of a detraining period. Subjects who trained without the drug lost a significant amount of their muscular forces following the detraining period.

Clinically, anabolic steroids have been used to relieve pathological conditions involving excessive nitrogen loss and reduced protein synthesis (7,9). Interest has been further increased through the use of these steroids at the opposite end of the spectrum, i.e., in an effort to increase body mass to enhance physical performance. World-class power event athletes are reported to be using anabolic steroids as complements to training regimens. Early work in this area has been hampered by the lack of research concerning the residual effect of anabolic steroids. Two recent studies (1,2) reveal the possibility of biochemical as well as psychological ef-fects of anabolic steroids. Using a double-blind control, statistically significant increases in muscular force under the placebo condition, and significant changes in reflex components as a result of drug administration were observed.

The present study was designed to investigate the prolonged residual effects of an anabolic steroid (15 mg of methandrostenolone daily during four consecutive weeks) following cessation of drug administration and a 15 week detraining period.

METHOD

The population consisted of male weightlifters registered at the University of Massachusetts during the ed for publication March, 1973.

GIDEON ARIEL University of Massachusetts Department of Exercise Science Amherst, Massachusetts

1971-1972 school year. Twenty volunteers ranging in age from 19 to 25 served as subjects in this study. Their eight averaged 179.5 cm and their mean weight was 87.25 kg.

The twenty subjects were divided into two groups. Ten subjects in group 1 (experimental group) received 15 mg of methandrostenolone, an oral anabolic steroid, daily during four consecutive weeks, while the ten subjects in group 2 (control group) received no supplement.

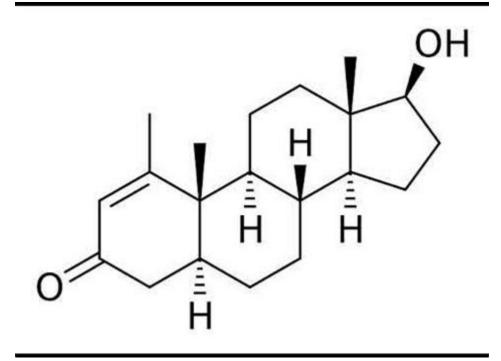

For a period of four weeks prior to the beginning of the drug administration, all subjects lifted weights five days a week. They were tested on the seventh day for maximum lifts in the bench and military presses and the squat exercises. Maximum dynamic contractile force measurements were determined by 1-RM. Technique used in performing the three lifts were those prescribed by the Amateur Athletic Union rules for weightlifting competition. The anabolic steroid was administered during a subsequent four week training period which was then followed by a 15-week detraining period. During the training period the subjects exercised five times per week for approximately two hours each day according to a program designed to work the major muscle groups of the body utilizing a progressive over-load principle. The detraining period extended from June through August during which no training was reported by any of the subjects. This period constitutes the traditional summer vacation schedule, and since the subjects were absent from the campus, no formed regulatory procedures governing their activity were possible

Analysis of variance was used in order to analyze the differences of strength levels between the training period and the detraining period for each group.

Figure 1 presents the strength level differences during the training period and following the detraining period. Table 1 presents the analysis of variance for the data and Table 2 presents the muscular force levels for the experimental and the control groups.

In the bench-press exercise, the experimental group lost 6.6 kg of mean force while the control group lost a mean force of 19.9 kg. In the military press, the experimental group lost a mean force of 4.76 kg compared with 9.52 kg for the control group. In the squat exercise,
